Towards English-to-Czech MT via Tectogrammatical Layer

Ondřej Bojar, Silvie Cinková, Jan Ptáček

Abstract

We present an overview of an English-to-Czech machine translation system. The system relies on transfer at the tectogrammatical (deep syntactic) layer of the language description. We report on the progress of linguistic annotation of English tectogrammatical layer and also on the first end-to-end evaluation of our syntax-based MT system.

1. Introduction

Current state-of-the-art machine translation (MT) systems are mostly statistical and phrase-based\(^1\). In recent years the performance of (surface) syntax-based systems has improved and as a result they are approaching state-of-the-art performance levels (Zollmann and Venugopal, 2006, Quirk and Menezes, 2006, Chiang, 2005).

Our long-term goal is to improve English-Czech MT quality by introducing a transfer step at a deep syntactic layer, making explicit use of linguistic theories and annotated data. For the time being, parts of the annotated data as well as the whole pipeline of automatic deep syntactic analysis, syntactic transfer and a generation component still constitute just work in progress. Nevertheless, we are able to deliver a first end-to-end evaluation that will serve as a baseline for the future improvements of the system.

In Section 2, we give a brief overview of the tectogrammatical representation. Section 3 summarizes our ongoing efforts in annotating English texts at the tectogrammatical layer. In Section 4, we describe both formal and implementational aspects of our MT system and Section 5 compares and discusses automatically assessed translation quality of several configurations of our system.

\(^1\)See NIST evaluation: http://www.nist.gov/speech/tests/mt/
2. Overview of the Tectogrammatical Representation

2.1. Functional Generative Description and Treebank Annotation

The tectogrammatical language representation is an implementation of the Functional Generative Description (FGD, Sgall, Hajičová, and Panevová, 1986). FGD has been implemented in treebank annotations. The Prague Dependency Treebank (PDT 2.0, Hajič et al., 2006) consists of three interlinked annotation layers, corresponding to the three FGD-original levels: the morphological layer (m-layer; 2 million words), the analytical layer (a-layer, an auxiliary step reflecting surface syntax; 1.5 million words) and the tectogrammatical layer (t-layer; 0.8 million words).

The FGD as well as the treebank annotation focus on the tectogrammatical language (t-) level. Being a transition between syntax and semantics (sometimes also referred to as underlying syntax/deep syntax), the tectogrammatical language level captures the linguistic meaning of each sentence, describing mutual syntactic and semantic relations between the respective words in a sentence, including those of coreference and topic-focus articulation in a broader context scope. FGD has a strong valency theory (Panevová, 1980, Panevová, 1974, Panevová, 1975). The valency theory of FGD assigns valency frames to verbs, nouns, adjectives and certain types of adverbs, assigning semantic roles to their complementations.

2.2. Trees, Nodes and Edges

In the treebank annotation, every sentence is represented as a rooted dependency tree with labeled nodes and edges. The tree reflects the underlying (deep) structure of the sentence. Several types of edges specify whether the relation between two nodes is a dependency relation or not (e.g. the relation between the sentence predicate and an interjection or a disjunct is not that of dependency, although the predicate and the other node are connected by an edge).

Unlike the surface-syntax representation (a-layer), only autosemantic words\(^2\) have their own nodes in the tectogrammatical tree structures. Function words like auxiliaries, subordinating conjunctions and prepositions as well as several cognitive, syntactic and morphological categories are attached to the respective nodes as a set of attribute-value pairs. The presence or absence of an attribute in a given node is determined by its node type.

2.3. Valency

Each occurrence of a part of speech that is considered to have valency is assigned a valency frame from a valency lexicon, interlinked with the data\(^3\). Obligatory complementations that are not present in the surface representation of the sentence get their tectogrammatical repre-

\(^2\)Several artificially generated complementary nodes for coordination, apposition, reciprocity, etc., and the technical root node also have their own t-nodes, although they do not necessarily have a corresponding node in the surface structure.

\(^3\)In the current annotation, this is restricted to verbs and certain types of nouns.
sentations by means of artificially added nodes. These nodes specify whether the missing information can be retrieved from the context (anaphora/cataphora, textual ellipsis) or whether it is only implied by common knowledge.

2.4. Machine Translation via Tectogrammatical Layer

Figure 1 illustrates an overall scheme of our MT system. The rationale to introduce additional layers of formal language description is to bring the source and target language closer to each other (see Figure 2). If the layers are designed appropriately, the transfer step will be easier to implement because (among others):

- t-structures exhibit less divergences, fewer structural changes will be needed in the transfer step.
- t-nodes correspond to autosemantic words only, all auxiliary words are identified in the source language and generated in the target language using language-dependent grammatical rules between t- and a- layers.
- t-nodes contain word lemmas, the whole morphological complexity of either of the languages is handled between m- and a- layers.
- t-layer abstracts away word-order issues, explicitly encoding topic-focus articulation (given/new) in node order.

3. English Tectogrammatical Layer: Ongoing Work

3.1. Prague Czech-English Dependency Treebank

The tectogrammatical representation remains language-specific in many concrete annotation decisions. Even so, its basic concepts are believed to be applicable to most languages. To prove this assumption, a parallel Czech-English treebank is being built. The Prague Czech-English Dependency Treebank (PCEDT 2.0) is based on PCEDT 1.0 (Cufín et al., 2004), which comprises the Penn Treebank II - Wall Street Journal section (Marcus et al., 1994) converted into dependency trees on the a-layer, and a corpus of its Czech translations, parsed in the same
He was troubled by insects etc. Obtěžoval ho hmyz apod.

Figure 2. A pair of English and Czech t-trees of the same sentence.

way as PDT 1.0 (Hajič et al., 2001) was. As PDT 2.0 came into existence, the parallel texts were re-parsed to comply with the new format of PDT 2.0, and manual annotation of the automatically pre-processed t-layer trees was launched for both languages.

3.2. Prague English Dependency Treebank

The English counterpart (referred to as the Prague English Dependency Treebank, PEDT) comprises approx. 50 000 dependency trees, which have been obtained by an automatic conversion of the original Penn Treebank II constituency trees into FGD-compliant a-layer trees. These a-layer trees have been automatically converted into t-layer trees. EngVallex (Cinková, 2006), a valency lexicon of verbs contained in PTB-WSJ, was obtained by a semi-automatic conversion of the PropBank-Lexicon (Palmer, Gildea, and Kingsbury, 2005, Palmer et al., 2004) into an FGD-compliant valency lexicon (following the structure of the Czech PDT-Vallex (Hajič et al., 2003)) and its manual adjustment.

3.3. Annotation Manual

Three annotators and a coordinator have been working on the adaptation of the Czech annotation guidelines into English. An annotation manual for the English tectogrammatical representation was released (Cinková et al., 2006)\textsuperscript{4}. So far, the annotation has concentrated on the following issues:

1. correct tree structure, including but not limited to:
   (a) rules for coordination, apposition, parenthesis
   (b) some specific constructions like comparison, restriction, consecutive clauses with quantifiers etc.

\textsuperscript{4}http://ufal.mff.cuni.cz/~cinkova/TR_En.pdf
3.4. Annotation Process

Three Czech annotators had first been trained in the Czech annotation and their proficiency in English had been checked before entering the English annotation. The annotation tool TrEd\(^5\), used in the Czech annotation, was adopted to the specific features of the English annotation. Later on, the two configurations were re-unified to make it possible for the annotators to switch languages without having to learn two different ways of annotation with TrEd. This preparatory stage lasted from spring to fall 2006. The actual annotation was launched in September 2006.

The annotators are supposed to deliver 500 trees per month including the test files for agreement measurements, which should ensure about one half of PTB-WSJ to be manually annotated by 2008. Being slightly behind the schedule, we appointed and trained several new annotators. Simultaneously, special attention is being paid to tree pre-processing in order to decrease the extent of the manual annotation work. As the annotation manual has become quite stable now it is possible to formulate additional rules for the conversion of the original constituency trees into tectogrammatical trees, exploiting the rich original linguistic markup of PTB-WSJ in more depth than done so far, e.g. regarding cleft sentences and verb control.

4. Tree-to-tree Transfer

4.1. Synchronous Tree Substitution Grammars

Synchronous Tree Substitution Grammars (STSG) were introduced by Hajič et al., 2002 and later formalized by various authors. The exact definitions we use are summarized in Bojar and Čmejrek, 2007. STSG capture the basic assumption of syntax-based MT that a valid translation of an input sentence can be obtained by local structural changes of the input syntactic tree (and translation of node labels). Some training sentences may violate this assumption because human translators do not always produce literal translations but we are free to ignore such sentences.

As illustrated in Figure 3, STSG describe the tree transformation process using the basic unit of treelet pair. Both the source and the target tree are decomposed into treelets that fit

\(^5\)http://ufal.mff.cuni.cz/pdt2.0/doc/tools/tred/
Figure 3. A sample pair of analytical trees synchronously decomposed into treelets.

Figure 4. A sample analytical treelet pair.

together. Each treelet can be considered as representing a minimum translation unit. A treelet pair such as depicted in Figure 4 represents the structural and lexical changes necessary to transfer local context of a source tree into a target tree.

Each node in a treelet is either internal (●, constitutes treelet internal structure and carries a lexical item) or frontier (○, represents an open slot for attaching another treelet). Frontier nodes are labelled with state labels (such as "_Sb" or "_NP"), as is the root of each treelet. A treelet can be attached at a frontier node only if its root state matches the state of the frontier.

A treelet pair (i.e. a rule in the synchronous grammar) describes also the mapping of the frontier nodes. A pair of treelets is always attached synchronously at a pair of matching frontier nodes.

Depending on our needs, we can encode ordering of nodes as part of each treelet. If only local ordering is used (i.e. we record the position of a parent node among its sons), the output tree will be always projective (see Sgall, Hajičová, and Panevová, 1986, p. 152). If we record global ordering of all nodes in a treelet, the final output tree may contain non-projectivities introduced by non-projective treelets (the attaching operation itself is assumed to be projective).

STSG is generic enough to be employed at or across various layers of annotation (e.g. En-
O. Bojar, S. Cinková, J. Ptáček Towards E → C MT via Tectogrammatical Layer (57–68)

glish t-tree to Czech t-tree or English a-tree to Czech a-tree). Our primary goal is to perform transfer at the tectogrammatical layer.

4.2. STSG Decoder

The task of STSG “decoder” is to find the most likely target tree, given a source tree and a dictionary of treelet pairs.

Our current version of the decoder considers all possible decompositions of input tree. We traverse the input tree top-down, using the dictionary of treelet pairs to produce the output tree by attaching corresponding right hand treelets to open frontiers. Another option is to traverse the tree in bottom-up fashion in a parsing-like algorithm, as sketched in Čmejrek, 2006.

The research prototype of the transfer system can be obtained at the following URL: http://ufal.mff.cuni.cz/euromatrix/

4.3. Estimating STSG Model Parameters

Bojar and Čmejrek, 2007 provides formal details and expectation-maximization algorithms for training STSG using a parallel treebank. Considerations and experiments with this alignment system reported in Bojar, Janůček, and Týnovský, 2008 unfortunately reveal serious problems with scalability of the system to moderately sized parallel corpora. If all possible decompositions of trees to treelets are taken into account, the lexicon of extracted treelet pairs is too big to fit in memory. If the extracted rules are heuristically pruned based on word-to-word alignment, memory requirements significantly decrease but so does the coverage of the rules: many tree pairs in the training data become unreachable using the lexicon of treelet pairs that survived the pruning. A plausible balance between the detail and coverage of the treelet pairs is still to be searched for. Ultimately, we may need to resort to a two-phase approach of preliminary alignment using very coarse-grained information from the trees (to avoid excessive number of distinct treelets in the beginning) followed by the selection of a single best choice from the set of preliminary alignments using more details from the data.

For the time being we restrict our training method to a heuristic based on GIZA++ (Och and Ney, 2000) word alignments. For each tree pair in the training data, we first read off the sequence of node labels and use GIZA++ tool to extract a possibly N-N node-to-node-alignment. Then we extract all treelet pairs from each aligned tree pair such that all the following conditions are satisfied:

- each treelet may contain at most 5 internal and at most 7 frontier nodes (the limits are fairly arbitrary),
- each internal node of each treelet, if aligned at all, must be aligned to a node in the other treelet,
- the mapping of frontier nodes has to be a subset of the node-alignment,
- each treelet must satisfy STSG property: if a node in the source tree is used as an internal node of the treelet, all immediate dependents of the node have to be included in the treelet as well (either as frontier or internal nodes). In other words, we assume no tree
adjunction operation was necessary to construct the training sentence.

All extracted treelet pairs and basic co-occurrence statistics constitute our “translation table”.

4.4. Methods of Back-off

As expected, and also pointed out by Čmejrek, 2006, the additional structural information boosts data-sparseness problem. Many source treelets in the test corpus were never seen in our training data. To tackle the problem, our decoder utilizes a sequence of back-off models, i.e. a sequence of several translation tables where each subsequent table is based on less fine-grained description of the input tree.

Given a source treelet, we first search an “exact-match” translation table. If no translation candidate can be found, we disregard some of the detailed node attributes (such as verbal tense etc.) in the source treelet and search for a correspondingly reduced translation table. We also experiment with an alternative direction of source treelet simplification: we keep the full detail of internal nodes but remove all frontier nodes. When a target treelet is found (with no frontier nodes, because the source treelet we searched for had no frontier nodes either), we insert the original number of frontier nodes on the fly, guessing both their position in the treelet and their label using simple local statistics. As a last resort back-off, we keep the internal nodes in the source treelet untranslated and just guess target-side labels of all frontiers. The order and level of detail of the back-off methods is fixed but easily customizable in a configuration file.

4.5. Generating Surface from Czech Tectogrammatical Trees

The purpose of the generation component is to express the meaning given by the target t-tree in a sentence of the target language. In the terms of Figure 1, our objective is the transition given by the right side of the translation triangle.

We decompose the generation into a sequence of seven linguistically motivated steps: Formeme Selection, Agreement, Adding Functional Words (prepositions, subordinating conjunctions and other auxiliaries), Inflexion, Word Order, Punctuation and Vocalization. During each step the input t-tree is gradually changing - new node attributes and/or new nodes are added. After the last step, the nodes are ordered appropriately and each node bears a computed word form. The resulting sentence is then simply obtained by concatenation.

The Formeme Selection phase is where the syntactic shape of the final sentence is grounded. The input t-tree is traversed in depth-first fashion and a suitable morphosyntactic (surface) form is selected for each node. From the full repertoire of surface forms available in Czech language, a subset was selected and is implemented in the generator. Surface forms are identified in the system by a distinguishable label, which we call formeme. The formeme is stored as an attribute of a t-node once particular surface realization is picked out. Possible formeme values are for instance: simple case gen (genitive case), prepositional case pod+7 (preposition pod/under and instrumental case), adj (syntactic adjective), že+v-fin (subordinating clause introduced with subordinating conjunction že), etc.
Surface forms suitable for a particular t-node are restricted both by syntax and semantics. The syntactic nature is given by the governor’s and its own part of speech. As far as semantics is concerned, a particular choice of meaning-bearing preposition or subordinate conjunction is determined by an attribute of t-node called functor. Additional constraints can also be specified in a valency frame of t-node’s governor; the frame is picked up from a valency dictionary. The six remaining steps of generation procedure materialize the syntactic and morphological aspects prescribed by the formeme.

Computation of word forms is accomplished using morphological tools characterized by Hajič, 2004. Vocalization rules specifying whether to append a vowel -e/-u to selected prepositions are based on Petkevič, 1995. A detailed description of the generation component is given in (Ptáček and Žabokrtský, 2006).

5. Experimental Results

Table 1 reports the BLEU (Papineni et al., 2002) scores of several configurations of our system. For the purposes of comparison with a phrase based system tuned for English-to-Czech, we train and test our system on the News Commentary corpus as available for the ACL 2007 workshop on machine translation (WMT)\(^6\). We use BLEU to compare the lowercased output of the system to a single lowercased reference translation.\(^7\)

The values in column Generation indicate how strongly is the final production of string of words driven by an n-gram language model (LM). For phrase-based approaches, LM is a vital component. For our transfer to Czech a-layer, our decoder uses LM to score partial trees when enough consecutive internal nodes have been established. The generation component described in Section 4.5 employs no LM and has no access to the target side of the training corpus.

5.1. Discussion and Future Research

At first sight, our preliminary results support common worries that with a more complex system it is increasingly difficult to obtain good results. However, we are well aware of many limitations of our current experiments:

1. BLEU is known to favour methods employing n-gram based language models (LMs). In future experiments we plan to attempt both, employing some LM-based rescoring when generating from the t-layer, as well as using other automatic metrics of MT quality.
2. All components in our setup deliver only the single best candidate. Any errors will therefore accumulate over the whole pipeline. In the future, we would like to pass and accept several candidates, allowing each step in the calculation to do any necessary rescoring.
3. The rule-based generation system has been designed to generate from full-featured manual Czech tectogrammatical trees from the (monolingual) PDT. There are so far no man-

\(^6\)http://www.statmt.org/wmt07/

\(^7\)For methods using the generation system as described in section 4.5, we tokenize the hypothesis and the reference using the rules from the official NIST mteval-v11b.pl script. For methods that directly produce sequence of output tokens, we stick to the original tokenization.
Table 1. Preliminary English-to-Czech BLEU scores for syntax-based MT evaluated on Dev and DevTest datasets of ACL 2007 WMT shared task.

Transfer Mode                  Generation     Dev      DevTest
English t → Czech t preserving structure  rule-based  5.38±0.43  5.12±0.49
English t → Czech t changing structure   rule-based  5.14±0.43  4.74±0.46
English t → Czech a                  LM-guided    7.01±0.50  6.27±0.56
English a → Czech t                  rule-based    3.21±0.37  3.18±0.35
English a → Czech a                  LM-guided    9.88±0.58  8.61±0.57

Vanilla                             LM-driven    -        12.9±0.6
Factored to improve target morphology LM-driven    -        14.2±0.7

Surprisingly, preserving the structure of English t-tree achieves (insignificantly) better BLEU score than allowing the decoder to use larger treelets to produce structurally different Czech t-trees. One possible explanation is that our current heuristic tree-alignment method performs poorly for t-trees. For all other modes of transfer (t→a, a→t, a→a), tree structure modifications gain significant improvements and we use them.

6. Conclusion

We have described the current status of our ongoing effort to translate from English to Czech via deep syntactic (tectogrammatical) structure. The process involves adaptation of the tectogrammatical layer definition for English, parallel treebank annotation and automatic procedures of source sentence analysis, tree-based transfer and target sentence generation.

Our first empirical results do not reach the phrase-based benchmark and we give several reasons why this is the case. However, the presented system is a finished pipeline that establishes a baseline and makes it possible to evaluate how modifications to individual components influence the end-to-end performance in syntax-based machine translation.
7. Acknowledgment

The work on this project was partially supported by the grants FP6-IST-5-034291-STP (EuroMatrix), GA405/06/0589, 1ET101120503, 1ET201120505, and GAUK 7643/2007. We would like to thank Zdeněk Žabokrtský for his rules performing automatic annotation of English t-layer.
