Abstract

Mapping documents into an interlingual representation can help bridge the language barrier of a cross-lingual corpus. Previous approaches use aligned documents as training data to learn an interlingual representation, making them sensitive to the domain of the training data. In this paper, we learn an interlingual representation in an unsupervised manner using only a bilingual dictionary. We first use the bilingual dictionary to find candidate document alignments and then use them to find an interlingual representation. Since the candidate alignments are noisy, we develop a robust learning algorithm to learn the interlingual representation. We show that bilingual dictionaries generalize to different domains better: our approach gives better performance than a word by word translation method or Canonical Correlation Analysis (CCA) trained on a different domain.

1 Introduction

The growth of text corpora in different languages poses an inherent problem of aligning documents across languages. Obtaining an explicit alignment, or a different way of bridging the language barrier, is an important step in many natural language processing (NLP) applications such as: document retrieval (Gale and Church, 1991; Rapp, 1999; Ballesteros and Croft, 1996; Munteanu and Marcu, 2005; Vu et al., 2009), Translation Mining (Klementiev and Roth, 2006; Hermjakob et al., 2008; Udupa et al., 2009; Ravi and Knight, 2009) and Multilingual Web Search (Gao et al., 2008; Gao et al., 2009).

Aligning documents from different languages arises in all the above mentioned problems. In this paper, we address this problem by mapping documents into a common subspace (interlingual representation)\(^1\). This common subspace generalizes the notion of vector space model for cross-lingual applications (Turney and Pantel, 2010).

There are two major approaches for solving the document alignment problem, depending on the available resources. The first approach, which is widely used in the Cross-lingual Information Retrieval (CLIR) literature, uses bilingual dictionaries to translate documents from one language (source) into another (target) language (Ballesteros and Croft, 1996; Pirkola et al., 2001). Then standard measures such as cosine similarity are used to identify target language documents that are close to the translated document. The second approach is to use training data of aligned document pairs to find a common subspace such that the aligned document pairs are maximally correlated (Susan T. Dumais, 1996; Vinokourov et al., 2003; Mimno et al., 2009; Platt et al., 2010; Haghigi et al., 2008).

Both kinds of approaches have their own strengths and weaknesses. Dictionary based approaches treat source documents independently, i.e., each source language document is translated independently of other documents. Moreover, after translation, the relationship of a given source document with the rest of the source documents is ignored. On the other hand, supervised approaches use all the source and target language documents to infer an interlingual

\(^1\)We use the phrases “common subspace” and “interlingual representation” interchangeably.
representation, but their strong dependency on the training data prevents them from generalizing well to test documents from a different domain.

In this paper, we propose a technique that combines the advantages of both these approaches. At a broad level, our approach uses bilingual dictionaries to identify initial noisy document alignments (Sec. 2.1) and then uses these noisy alignments as training data to learn a common subspace. Since the alignments are noisy, we need a learning algorithm that is robust to the errors in the training data. It is known that techniques like CCA overfit the training data (Rai and Daumé III, 2009). So, we start with an unsupervised approach such as Kernelized Sorting (Quadrianto et al., 2009) and develop a supervised variant of it (Sec. 2.2). Our supervised variant learns to modify the within language document similarities according to the given alignments. Since the original algorithm is unsupervised, we hope that its supervised variant is tolerant to errors in the candidate alignments. The primary advantage of our method is that, it does not use any training data and thus generalizes to test documents from different domains. And unlike the dictionary based approaches, we use all the documents in computing the common subspace and thus achieve better accuracies compared to the approaches which translate documents in isolation.

There are two main contributions of this work. First, we propose a discriminative technique to learn an interlingual representation using only a bilingual dictionary. Second, we develop a supervised variant of Kernelized Sorting algorithm (Quadrianto et al., 2009) which learns to modify within language document similarities according to a given alignment.

2 Approach

Given a cross-lingual corpus, with an underlying unknown document alignment, we propose a technique to recover the hidden alignment. This is achieved by mapping documents into an interlingual representation. Our approach involves two stages. In the first stage, we use a bilingual dictionary to find initial candidate noisy document alignments. The second stage uses a robust learning algorithm to learn a common subspace from the noisy alignments identified in the first step. Subsequently, we project all the documents into the common subspace and use maximal matching to recover the hidden alignment. During this stage, we also learn mappings from the document spaces onto the common subspace. These mappings can be used to convert any new document into the interlingual representation. We describe each of these two steps in detail in the following two sub sections (Sec. 2.1 and Sec. 2.2).

2.1 Noisy Document Alignments

Translating documents from one language into another language and finding the nearest neighbours gives potential alignments. Unfortunately, the resulting alignments may differ depending on the direction of the translation owing to the asymmetry of bilingual dictionaries and the nearest neighbour property. In order to overcome this asymmetry, we first turn the documents in both languages into bag of translation pairs representation.

We follow the feature representation used in Jagarlamudi and Daumé III (2010) and Boyd-Graber and Blei (2009). Each translation pair of the bilingual dictionary (also referred as a dictionary entry) is treated as a new feature. Given a document, every word is replaced with the set of bilingual dictionary entries that it participates in. If \( D \) represents the TFIDF weighted term \( \times \) document matrix and \( T \) is a binary matrix matrix of size \( no\_of\_dictionary\_entries \times vocab\_size \), then converting documents into a bag of dictionary entries is given by the linear operation \( X^{(t)} \leftarrow T D_{2} \).

After converting the documents into bag of dictionary entries representation, we form a bipartite graph with the documents of each language as a separate set of nodes. The edge weight \( W_{ij} \) between a pair of documents \( x_{i}^{(t)} \) and \( y_{j}^{(t)} \) (in source and target language respectively) is computed as the Euclidean distance between those documents in the dictionary space. Let \( \pi_{ij} \) indicate the likeliness of a source document \( x_{i}^{(t)} \) is aligned to a target document \( y_{j}^{(t)} \). We want each document to align to at least one document from other language. Moreover, we want to encourage similar documents to align to each other. We can formulate this objective and the constraints as the following minimum cost flow
problem (Ravindra et al., 1993):

$$\arg\min_{\pi} \sum_{i,j=1}^{m,n} W_{ij} \pi_{ij}$$  \hspace{1cm} (1)

$$\forall i \sum_{j} \pi_{ij} = 1 \quad ; \quad \forall j \sum_{i} \pi_{ij} = 1$$

$$\forall i, j \quad 0 \leq \pi_{ij} \leq C$$

where $C$ is some user chosen constant, $m$ and $n$ are the number of documents in source and target languages respectively. Without the last constraint ($\pi_{ij} \leq C$) this optimization problem always gives an integral solution and reduces to a maximum matching problem (Jonker and Volgenant, 1987). Since this solution may not be accurate, we allow many-to-many mapping by setting the constant $C$ to a value less than one. In our experiments (Sec. 3), we found that setting $C$ to a value less than 1 gave better performance analogous to the better performance of soft Expectation Maximization (EM) compared to hard-EM. The optimal solution of Eq. 1 can be found efficiently using linear programming (Ravindra et al., 1993).

### 2.2 Supervised Kernelized Sorting

Kernelized Sorting is an unsupervised technique to align objects of different types, such as English and Spanish documents (Quadrianto et al., 2009; Jagaralmodi et al., 2010). The main advantage of this method is that it only uses the *intra*-language document similarities to identify the alignments across languages. In this section, we describe a supervised variant of Kernelized Sorting which takes a set of candidate alignments and learns to modify the intra-language document similarities to respect the given alignment. Since Kernelized Sorting does not rely on the inter-lingual document similarities at all, we hope that its supervised version is robust to noisy alignments.

Let $X$ and $Y$ be the TF-IDF weighted term × document matrices in both the languages and let $K_x$ and $K_y$ be their linear dot product kernel matrices, i.e., $K_x = X^T X$ and $K_y = Y^T Y$. Let $\Pi \in \{0,1\}^{m \times n}$ denote the permutation matrix which captures the alignment between documents of different languages, i.e. $\pi_{ij} = 1$ indicates documents $x_i$ and $y_j$ are aligned. Then Kernelized Sort-

ing formulates $\Pi$ as the solution of the following optimization problem (Gretton et al., 2005):

$$\arg\max_{\Pi} \text{tr}(K_x \Pi K_y \Pi^T)$$  \hspace{1cm} (2)

$$\quad = \arg\max_{\Pi} \text{tr}(X^T X \Pi Y^T Y \Pi^T)$$  \hspace{1cm} (3)

In our supervised version of Kernelized Sorting, we fix the permutation matrix (to say $\hat{\Pi}$) and modify the kernel matrices $K_x$ and $K_y$ so that the objective function is maximized for the given permutation. Specifically, we find a mapping for each language, such that when the documents are projected into their common subspaces they are more likely to respect the alignment given by $\hat{\Pi}$. Subsequently, the test documents are also projected into the common subspace and we return the nearest neighbors as the aligned pairs.

Let $U$ and $V$ be the mappings for the required subspace in both the languages, then we want to solve the following optimization problem:

$$\arg\max_{U,V} \text{tr}(X^T U U^T X \hat{\Pi} Y^T V V^T Y \hat{\Pi}^T)$$  \hspace{1cm} (4)

s.t. $U^T U = I$ & $V^T V = I$

where $I$ is an identity matrix of appropriate size. For brevity, let $C_{xy}$ denote the cross-covariance matrix (i.e. $C_{xy} = X \Pi Y^T$) then the above objective function becomes:

$$\arg\max_{U,V} \text{tr}(U U^T C_{xy} V V^T C_{xy}^T)$$  \hspace{1cm} (5)

s.t. $U^T U = I$ & $V^T V = I$

We have used the cyclic property of the trace function while rewriting Eq. 4 to Eq. 5. We use alternative maximization to solve for the unknowns. Fixing $V$ (to say $V_0$), rewriting the objective function using the cyclic property of the trace function, forming the Lagrangian and setting its derivative to zero results in the following solution:

$$C_{xy} V_0 V_0^T C_{xy}^T U = \lambda_u \ U$$  \hspace{1cm} (6)

For the initial iteration, we can substitute $V_0 V_0^T$ as identity matrix which leaves the kernel matrix unchanged. Similarly, fixing $U$ (to $U_0$) and solving the optimization problem for $V$ results:

$$C_{xy}^T V_0 U_0^T C_{xy} V = \lambda_v \ V$$  \hspace{1cm} (7)
In the special case where both $V_0 V_0^T$ and $U_0 U_0^T$ are identity matrices, the above equations reduce to
\[
C_{xy} C_{xy}^T U = \lambda_u U \quad \text{and} \quad C_{xy}^T C_{xy} V = \lambda_v V.
\]
In this particular case, we can simultaneously solve for both $U$ and $V$ using Singular Value Decomposition (SVD) as:
\[
USV^T = C_{xy}
\]
So for the first iteration, we do the SVD of the cross-covariance matrix and get the mappings. For the subsequent iterations, we use the mappings found by the previous iteration, as $U_0$ and $V_0$, and solve Eqs. 6 and 7 alternatively.

### 2.3 Summary

In this section, we describe our procedure to recover document alignments. We first convert documents into bag of dictionary entries representation (Sec. 2.1). Then we solve the optimization problem in Eq. 1 to get the initial candidate alignments. We use the LEMON\(^3\) graph library to solve the min-cost flow problem. This step gives us the $\pi_{ij}$ values for every cross-lingual document pair. We use them to form a relaxed permutation matrix ($\hat{P}$) which is, subsequently, used to find the mappings ($U$ and $V$) for the documents of both the languages (i.e. solving Eq. 8). We use these mappings to project both source and target language documents into the common subspace and then solve the bipartite matching problem to recover the alignment.

### 3 Experiments

For evaluation, we choose 2500 aligned document pairs from Wikipedia in English-Spanish and English-German language pairs. For both the data sets, we consider only words that occurred more than once in at least five documents. Of the words that meet the frequency criterion, we choose the most frequent 2000 words for English-Spanish data set. But, because of the compound word phenomenon of German, we retain all the frequent words for English-German data set. Subsequently we convert the documents into TFIDF weighted vectors. The bilingual dictionaries for both the language pairs are generated by running Giza++ (Och and Ney, 2003) on the Europarl data (Koehn, 2005).

Table 1: Accuracy of different approaches on the Wikipedia documents in English-Spanish and English-German language pairs. For CCA, we regularize the within language covariance matrices as $(1-\lambda)XX^T+\lambda I$ and the regularization parameter $\lambda$ value is also shown.

We follow the process described in Sec. 2.3 to recover the document alignment for our method.

We compare our approach with a dictionary based approach, such as word-by-word translation, and supervised approaches, such as CCA (Vinokourov et al., 2003; Hotelling, 1936) and OPCA (Platt et al., 2010). Word-by-word translation and our approach use bilingual dictionary while CCA and OPCA use a training corpus of aligned documents. Since the bilingual dictionary is learnt from Europarl data set, for a fair comparison, we train supervised approaches on 3000 document pairs from Europarl data set. To prevent CCA from overfitting to the training domain, we regularize it heavily. For OPCA, we use a regularization parameter of 0.1 as suggested by Platt et al. (2010). For all the systems, we construct a bipartite graph between the documents of different languages, with edge weight being the cross-lingual similarity given by the respective method and then find maximal matching (Jonker and Volgenant, 1987). We report the accuracy of the recovered alignment.

Table 1 shows accuracies of different methods on both Spanish and German data sets. For comparison purposes, we trained and tested CCA on documents from same domain (Wikipedia). It achieves 75% and 62% accuracies for the two data sets respectively but, as expected, it performed poorly when trained on Europarl articles. On the English-German data set, a simple word-by-word translation performed better than CCA and OPCA. For both the language pairs, our model performed better than word-by-word translation method and competitively with the

---

\(^3\)https://lemon.cs.elte.hu/trac/lemon
supervised approaches. Note that our method does not use any training data.

We also experimented with few values of the parameter $C$ for the min-cost flow problem (Eq. 1). As noted previously, setting $C = 1$ will reduce the problem into a linear assignment problem. From the results, we see that solving a relaxed version of the problem gives better accuracies but the improvements are marginal (especially for English-German).

4 Discussion

For both language pairs, the accuracy of the first stage of our approach (Sec. 2.1) is almost same as that of word-by-word translation system. Thus, the improved performance of our system compared to word-by-word translation shows the effectiveness of the supervised Kernelized sorting.

The solution of our supervised Kernelized sorting (Eq. 8) resembles Latent Semantic Indexing (Deerwester, 1988). Except, we use a cross-covariance matrix instead of a term × document matrix. Efficient algorithms exist for solving SVD on arbitrarily large matrices, which makes our approach scalable to large data sets (Warmuth and Kuzmin, 2006). After solving Eq. 8, the mappings $U$ and $V$ can be improved by iteratively solving the Eqs. 6 and 7 respectively. But it leads the mappings to fit the noisy alignments exactly, so in this paper we stop after solving the SVD problem.

The extension of our approach to the situation with different number of documents on each side is straight forward. The only thing that changes is the way we compute alignment after finding the projection directions. In this case, the input to the bipartite matching problem is modified by adding dummy documents to the language that has fewer documents and assigning a very high score to edges that connect to the dummy documents.

5 Conclusion

In this paper we have presented an approach to recover document alignments from a comparable corpora using a bilingual dictionary. First, we use the bilingual dictionary to find a set of candidate noisy alignments. These noisy alignments are then fed into supervised Kernelized Sorting, which learns to modify within language document similarities to respect the given alignments.

Our approach exploits two complimentary information sources to recover a better alignment. The first step uses cross-lingual cues available in the form of a bilingual dictionary and the latter step exploits document structure captured in terms of within language document similarities. Experimental results show that our approach performs better than dictionary based approaches such as a word-by-word translation and is also competitive with supervised approaches like CCA and OPCA.
